SERVICE MANUAL

- This **ARNOLD** precision machine vice is guaranteed for quality, and workmanship. It has been prepared for its correct operation through our established final assembly and test procedures. Care should be taken that it is used correctly to ensure the operators and other persons safety in the workplace.
- Each person involved in the unpacking, handling, operation and maintenance of this vice is required to have to read this service manual. This is to ensure safety at work compliance, and the correct understanding of the vice operation.
- The operator has to be minimum 18-years of age, it must be ensured that the operator is capable or has to be trained on the correct vice operation by someone more senior. The operator must be able to prove his capabilities for its handling and operation and have read and understood this service manual and keep it available for reference.

Personal protection.-

- Security shoes (steel toecap type).
- Protecting gloves.
- Machine guards, safety glasses.

Workplace .-

- The vice must be clamped firmly to the machine table to avoid movements during a machining operation.
- Ensure the vice jaw movements are not impeded in any way,keep the work area tidy.

Moving the vice.-

- Care should be taken when moving the vice. The operator must keep clear of the crane or other lifting equipment used.

Unpacking the vice .-

- When unpacking the vice it should be with the use of a crane with a magnet or other safe system. Care should be taken that the load is correctly distributed before fully lifting.
- The vice is wrapped in oiled paper for its protection during delivery. Ensure that when the oiled paper is removed from its base it is immediately placed on a "cleaned" machine table and clamped safely in position.

Cleaning and general maintenance..-

- To ensure the vice long operational life and the most favourable working conditions, it is essential that it is cleaned very regularly, after each machining cycle of swarf or machining sludge that can affect its correct operation.
The regular "cleaning" can be by pressure coolant gun or air gun. Together the use of a small brush to clear the jaw movement ways can generally be effective. Cleaning by industrial rag or paper can also usefully be done after a number of machining cycles. It must be understood that the efficient vice operation needs clear space for clamping and unclamping. **Attention:** never use chemical products which can damage the vice.

Operating features

The hydraulic Spindle unit is actioned by means of a crank which is fitted in the hexagonal housing arranged in part (123). When the crank is turned, threaded spindle (001) runs through the spindle shoe (040) pushing the movable jaw (033) until jaws (036) meet the workpiece to be clamped. When the threaded spindle (001) encounters a determined resistance it stops acting, but by keeping on with the cranking procedure it makes the coupling disc (019) detach from the coupling body (121) and thus the torque rod (123) - which is firmly attached by part (124) - to spindle sleeve (122) advances and consequently introduces the small piston (012) in the oil chamber A in order to create an overpressure.

The pressure produced by the oil pushes the large piston (008) which at the meantime pushes pushrod (002). The pushrod through pressure plate (034) and movable jaw (033) transmits the power developed by the hydraulic differential mechanism to the clamping jaw. This maximum pressure moment is produced once spindle sleeve (122) has run over the threaded cylinder (013) and stopped against cylinder (003). The moment this point is reached, it is useless trying to increase the hydraulic pressure by hammering on the crank or by trying any other procedure.

Hydraulic Power Setting

If along the time the pressure decreases due to oil leakage, oil chamber A should be set by following the steps stated below:

- 1 Disassemble the hydraulic spindle unit from the vise or from any other fixture it may happen to be attached on.
- 2 Remove allen set-screw (004).
- 3 Drive forward threaded spindle (001) by giving it one third of a turn in cylinder (003) until the threaded hole in the cylinder matches with the next slot on the main spindle.
- 4 Replace allen set-screw (004) and thus the setting procedure shall have been accomplished.

Hydraulic Oil Filling up

- 1 Disassemble the hydraulic spindle unit from the vise or from any other fixture it may happen to be attached on.
- 2 Remove allen set-screw (004).
- 3 Unscrew threaded spindle (001) being careful that preset tension spring (006) and belleville springs (007) do not fling off when the spindle is removed.
- 4 Remove allen set-screw (004) (on size 090 it is 014).
- 5 Clamp cylinder (003) and remove threaded cylinder (013).
- 6 Keep cylinder (003) in a vertical position and remove small piston (012) upwards.

- 7 Whenever filling up oil-chamber A, a disc must be made whose size may differ according to the type of vice involved (See Table).

Place cylinder (003) on a flat surface with its large opening on the said disc, and with the help of a small pin or still better by using air under pressure, push forward large piston (008) until it stops against the mentioned disc. If air pressure is used for this purpose, hold tightly the cylinder so it does not move due to the pressure applied.

DISC		
Type	Max. Ø	Height
0	27mm.	11mm.
1 and 2	35mm.	8mm.
3	45mm.	14mm.

- 8 Pour hydraulic oil into the chamber until its level reaches the upper edge of the opening. Oil chamber A should be completely free of **air bubbles**. To accomplish this, stir the oil gently with a clean prick, and refill again to reach the level stated above if it were necessary.

The hydraulic oil to be used should feature a viscosity of 6,5 E/50° C., type.

- 9 Now introduce gently small piston (012) into cylinder (003) by its chamfered end pushing it and creating a twisting movement at the meantime. Small piston (012) must be absolutely clean so as not to damage small seal (011).
- 10 Hold tight cylinder (003) and then screw in the threaded cylinder (013). The hole practized through the threaded cylinder (013) has to match with the oil chamber slot, but if they did not, then unscrew threaded cylinder (013) and give it a 180° turn for it features a double entry thread. If the threaded cylinder is screwed in through the proper thread entry, the openings shall certainly match with each other. Once the matching has been accomplished, replace allen set-screw (004) (on size 090 it is 014) and tighten it firmly.
- 11 The belleville springs (007) are to be replaced as shown in the corresponding drawing.
- 12 Screw in threaded spindle (001) with pushrod (002) and preset tension spring (006) into cylinder (003) until this group can not be driven ahead any more by hand. Followingly, threaded spindle (001) shall be advanced by screwing it into cylinder (003), until the second slot on the spindle matches with the hole tappeted in the cylinder. Screw (004) is now to be replaced and tightened so as to keep everything assembled properly.
- 13 After having filled up the hydraulic spindle with the proper oil, it should be actioned several times before it is reassembled for service routines.

The Hydraulic Spindle Unit Applied to Other Fixtures

If the hydraulic spindle unit were to be applied to any other fixture, the following important points are to be remembered:

The less the fixture strains elastically, the greater shall be the pressure obtainable from the spindle whose hydraulic travel comes only to about 1.8 mm. Such a short distance needs obviously a very rigid support to fulfill its purpose.

There is available a bush for the hydraulic spindle which can be acquired by the user if the spindle is applied to other fixtures.

If the fixture the Hydraulic spindle unit is to be applied on is provided with a connecting pin, the said pin should move freely in its guides or bushes.

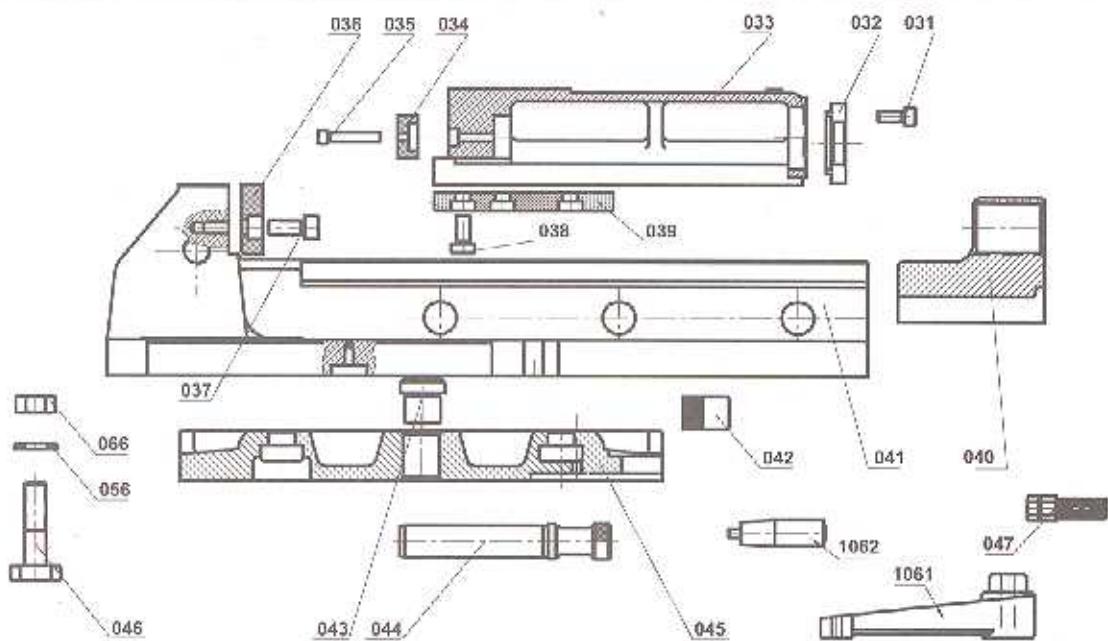

As not all fixtures are constructed so they feature rigid walls or supports, we suggest the use of a 0.2 to 6 Ton dynamometer to check the pressures it is able to stand.

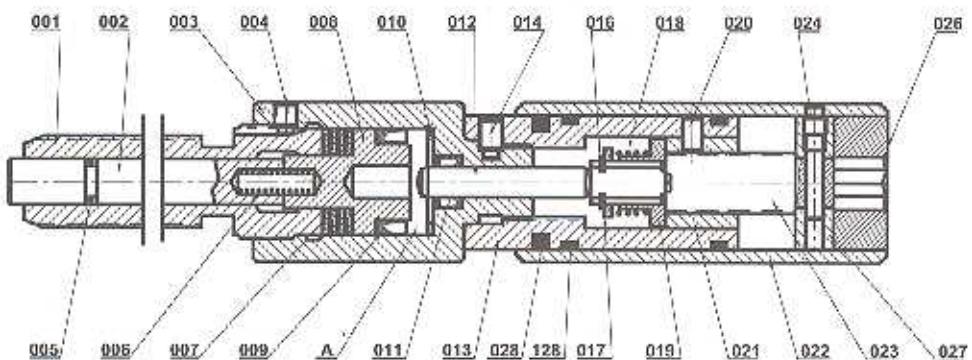

With a standard hydraulic spindle unit it will not be possible to stack tight metal sheets or similar parts if they are strained, since the spindle travel features only 1.8 mm. If either the hydraulic spindle or the vice will be used mainly for this purpose, we suggest the hydraulic **ARNOLD** spindle with presetting power control.

Remarks

If by any chance it were necessary to disassemble the spindle sleeve (122) (on size 090 it is 022), before removing it, it shall be necessary to INTRODUCE locking pin screw (124) (on size 090 it is 024) inside the threaded housing featured by part (123) (on size 090 it is 023). After the previous procedure, the sleeve can be removed and then unscrewed the mentioned locking pin screw (124).

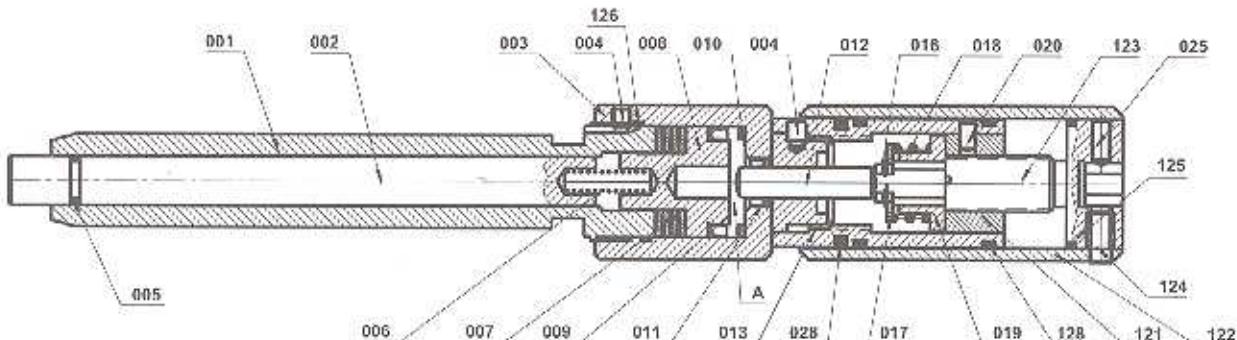

Whenever requiring spares for the said spindle, both the names and the reference numbers given to them in this instruction handbook are to be stated.
